(54) Power supply.

(57) An improved inverter AC power supply comprises a chopper providing a DC voltage from an AC source voltage and an inverter providing from the DC voltage a high frequency AC voltage to a load. The chopper comprises a pair of first and second switching elements operating to turn on and off for obtaining a periodically interrupted AC voltage which is rectified and smoothed to provide the DC voltage to the inverter. The inverter is arranged to share the first and second switching elements in common to the chopper and operates to drive the same switching elements for switching the DC voltage in order to provide a desired AC voltage to the load. The power supply is provided with an input power sensor monitoring an input power supplied to the chopper and an output power sensor monitoring an output power from the inverter to the load. A power controller is included for controlling to vary at least one of a switching frequency and a duty ratio for the first and second switching elements in accordance with the monitored chopper input power and inverter output power in the direction of equalizing the input and output powers.

POWER SUPPLY

TECHNICAL FIELD

The present invention is directed to a power supply, and more particularly to an inverter AC power supply which is connected to an commercial ac voltage source to provide therefrom through an ac-dc-ac conversion a high frequency AC voltage to a load with a maximum efficiency.

BACKGROUND ART

10 Inverter AC power supplies are known to comprise an ac-to-dc converter providing a dc voltage form a commercial ac source voltage and an inverter providing from the dc voltage a high frequency voltage for driving loads such as discharge lamps. It is also known to utilizes a chopper in the circuit which operates to chop the ac source voltage in providing the dc voltage to the inverter input for reducing the size of an inductor element necessary for improving a power factor of the circuit. In order to avoid duplication of
 15 components for the chopper and inverter, it has been proposed in the preceding European application No. 89 117 043.3 [EP publication No. 0 036 156 A2], to share switching elements for the chopper and inverter circuits. Although such prior power supply is found most effective in reducing the number of circuit components while assuring an improved power factor, it is rather difficult to control an input power W_{IN} to the chopper and an output power W_{OUT} from the inverter independently of one another due to the limitation
 20 that the switching elements are common to the chopper and the inverter. This poses another problem when the power supply suffers from considerable variations in the input power W_{IN} or output power W_{OUT} which may result from, for example, varying load conditions, fluctuations in the ac source voltage, or other factors. That is, when the input power to the chopper is by some reason reduced to have $W_{IN} < W_{OUT}$, considerable
 25 harmonics will appear in an input current from the AC source to thereby cause undesirable input distortion and eventually reduce the power factor. On the other hand, when the input power to the chopper is increased to have $W_{IN} > W_{OUT}$, the chopper output is correspondingly increased so as to apply such increased voltage to the switching elements and smoothing capacitors forming the chopper and the inverter. Consequently, it is required to utilize the switching element and the capacitors which can withstand such increased voltage for safe operation of the circuit. However, such components are unexceptionably
 30 expensive and will certainly add an extra cost to the power supply. Therefore, it is highly demanded to positively control for balancing the chopper input power W_{IN} and the inverter output power W_{OUT} , particularly in the power supply circuit utilizing the switching element common to the chopper and the inverter for the purpose of reducing the input distortion to a minimum, maintaining improved power factor, and preventing undue increase in cost.

35 It is therefore a primary object of the present invention to provide an improved inverter AC power supply which is capable of positively equalizing the chopper input power and the inverter output power for eliminating an undesirable input distortion to maintain an improved power factor, while assuring a safe operation with the use of less expensive circuit components.

In order to achieve the above objects, studies have been made to investigate a suitable control scheme
 40 for equalizing an input power and an output power in an inverter AC power supply circuit which comprises a chopper providing an input dc voltage from an ac source voltage and an inverter providing a high frequency ac voltage to a load from the dc voltage, and in which the chopper and the inverter share at least one switching element. Prior to discussing the control scheme, a brief explanation will be made to the power supply of the present invention for easy understanding of the present invention. Referring to FIG. 1, there is shown a basic circuit arrangement of the power supply invention, although the present invention is not limited thereto. As shown in the figure, the power supply comprises the chopper 1 connected through a low pass filter 3 to a commercial AC source voltage V_s , and the inverter 2 connected in circuit to invert the dc voltage from the chopper 1 for providing a high frequency AC voltage to a load, which is illustrated as one typical example to comprise an inductance L_3 and a fluorescent lamp FL with a capacitor C_4 . The chopper
 45 1 includes an inductor L_2 , a full-wave rectifier diode bridge of D_1 to D_4 , a pair of series connected switching elements Q_1 and Q_2 , and a pair of series connected capacitors C_2 and C_3 . The switching elements Q_1 and Q_2 are driven to alternately turn on and off at a high frequency in order to chop or repeat interrupting the AC voltage V_{IN} from the source voltage V_s , developing at inductor L_2 a resulting voltage which is then rectified through the full-wave rectifier to provide a DC voltage to the capacitors C_2 and C_3 while being smoothed thereat. The inverter 2 shares the switching elements Q_1 and Q_2 to switch the DC

voltage from the capacitors C_2 and C_3 for providing the resulting high frequency AC voltage to the load while the chopper 1 operates to provide the DC voltage to the capacitors C_2 and C_3 . FIG. 2 shows waveforms for input voltage V_{IN} and current I_{IN} , current I_{L2} through inductor L_2 , drive signals S_1 and S_2 for switching elements Q_1 and Q_2 , dc voltage V_c developed across each of capacitors C_2 and C_3 , and a load voltage V_L or current I_L . As shown in FIGS. 3A to 3D, and FIGS. 4A to 4D, the alternate switching on and off of the switching elements Q_1 and Q_2 produces within each half cycle of the AC voltage a first chopper mode alternated by a second chopper mode while effecting an inverter operation of providing the high frequency AC voltage to the load. The inverter operation is shown in FIG. 3A and 3C for positive half cycle of the AC source voltage V_{IN} and also in FIG. 4A and 4C for the negative half cycle of the AC source voltage V_{IN} . The first chopper mode is a pre-charge condition [FIG. 3B for the positive half cycle and FIG. 4B for the negative half cycle] in which one of the switching elements Q_1 (Q_2) is conductive to establish a closed loop of the AC voltage source V_s , the inductor L_2 , one of the diodes D_3 (D_4), and the one switching element Q_1 (Q_2) for storing the energy in the inductor L_2 . The second chopper mode is a charge condition [FIG. 3D for the positive half cycle and FIG. 4D for the negative half cycles in which the one of switching element Q_1 (Q_2) is non-conductive to establish a closed loop of the inductor L_2 , the one of the third and fourth diodes D_3 (D_4), the capacitor C_2 (C_3), one of the first and second diodes D_2 (D_1), and the AC voltage source V_s for releasing the energy from the inductor L_2 to charge the capacitor C_2 (C_3). In this manner, these modes or conditions repeat within each half cycle of the AC source voltage V_s to effect charging the capacitors C_2 and C_3 which provides the smoothed input voltage to the inverter. Thus, the switching elements Q_1 and Q_2 of the inverter can be best utilized equally within each one complete cycle of the input AC voltage as effecting the chopper operation for providing the DC voltage to the capacitors C_2 and C_3 . That is, Q_1 serves both for chopper and inverter operations while Q_2 serves only for the inverter operation during the positive half cycle, and Q_2 serves both for chopper and inverter operations while Q_1 serves only for the inverter operation during the negative half cycle of the AC source voltage. In this sense, both of the switching elements Q_1 and Q_2 are utilized common to the inverter and chopper operations. Further details of the circuit operation are fully explained in the preceding European application No. 89 117 043.3 [Published on March 30, 1990 under EP 0 036 156)] and are not repeated here.

Based upon the above power circuit having the switching elements common to the chopper and the inverter, it is contemplated to positively equalize the chopper input power W_{IN} and inverter output power W_{OUT} . In one version of the present invention, the chopper input power W_{IN} and inverter output power W_{OUT} are positively equalized by controlling to vary a switching frequency f and/or a duty ratio D of the switching elements with due consideration of simultaneous variations resulting both in the chopper input power W_{IN} and in the inverter output power W_{OUT} . The consequence of the individual controls are discussed in the below. Unless otherwise specified, the following description is based upon the power circuit of FIG. 1 having two switching elements Q_1 and Q_2 for driving the load composed of inductor L_3 , fluorescent lamp FL with capacitor C_4 .

I Frequency Control

W_{IN} and W_{OUT} can be represented respectively as functions of the switching frequency f , as shown in FIG. 5A, in which an operating frequency ranged is defined to be above a natural frequency f_c of the load. As apparent from the figure, both of W_{IN} and W_{OUT} show a monotonic decreasing relation to an increase in the switching frequency f within the available operating frequency range, and there is a frequency f_0 at which W_{IN} is equal to W_{OUT} . Also known from the figure is that W_{OUT} has a greater gradient or shows a greater ratio of change than W_{IN} relative to the change in the frequency f , i.e.,

$$\frac{d}{df} W_{OUT} > \frac{d}{df} W_{IN}$$

50

Therefore, it is found that the frequency control is suitable for varying W_{OUT} with a small change in W_{IN} .

II Duty Ratio Control

Duty ratio D is defined as a ratio of the on-time period to one complete cycle of the switching element. Since the power supply circuit includes two switching elements, the duty ratio can be defined in two

different manners, one is for the case where the two switching elements Q_1 and Q_2 having the same on-time period, the other is for the case where they have differing on-time periods which are complementary to one another, i.e., the on-period of the one switching element corresponds to the off-period of the other switching element.

5

II-A Duty ratio control with the same on-time period for Q_1 and Q_2 :

Due to the restriction of the inverter circuit in which the switching elements Q_1 and Q_2 should not be simultaneously turned on for protection against short-circuiting, the duty ratio D has to be less than 50%. Within a controllable duty ratio range below 50%, W_{IN} and W_{IN} show monotonic increasing relation to the increasing duty ratio D , as shown in FIG. 8. It is found from the figure that there is a particular point d_s adjacent $D = 50\%$ at which W_{IN} is equal to W_{IN} and that W_{IN} has a greater gradient or shows greater ratio of change than W_{OUT} in the vicinity of $D = 50\%$, in relation to the change in duty ratio D , i.e..

15

$$\frac{d}{dD} W_{IN} > \frac{d}{dD} W_{OUT}$$

20 Therefore, it is revealed that the duty ration control is suitable for varying W_{IN} with a small change in W_{OUT} .

II-B Duty ratio control with differing on time periods in complementary relation between Q_1 and Q_2 :

25 In this control, the two switching elements Q_1 and Q_2 are driven in such a manner that on-time period of one switching element corresponds to the off-time period of the other switching element, as illustrated in FIG. 9A where Q_1 and Q_2 have the same on-time period $T/2$ and FIG. 9B where Q_1 and Q_2 have differing on-time periods X_{ON} and $T-X_{ON}$ in complementary relation. Since there could be two definitions of duty ratio for the two switching elements with this control, duty ratio D is defined as directed to one of the switching elements which is currently responsible for the chopper operation. It is noted at this time that the switching elements Q_1 and Q_2 responsible for the chopper operation will alternate in synchronism with the polarity reversal in the AC source voltage V_S , as discussed in the above. That is, during positive half cycle of the input AC voltage V_{IN} , the switching element Q_1 is responsible for the chopper and inverter operations, while the switching element Q_2 is responsible only for the inverter operation. During the negative half cycle of the input voltage V_{IN} , the switching element Q_2 turns to be responsible for the chopper and inverter operations, while the switching element Q_1 is responsible only for the inverter operation. With this definition of the duty ratio D , the chopper input power W_{IN} and the inverter output power W_{OUT} show also monotonic increasing relation to the increasing duty ratio D , as shown in FIG. 5B. It is found from the figure that there is a particular point d_c adjacent $D = 50\%$ at which W_{IN} is equal to W_{IN} and that W_{IN} has a greater gradient or shows greater ratio of change than W_{OUT} in the vicinity of $D = 50\%$, in relation to the change in duty ratio D , i.e.,

$$\frac{d}{dD} W_{IN} > \frac{d}{dD} W_{OUT}$$

45

Therefore, it is also revealed that the duty ratio control is suitable for varying W_{IN} with a small change in W_{OUT} . In view of the above behaviors of W_{IN} and W_{OUT} in relation to the switching frequency f and duty ratio D of the switching elements, it is concluded that the frequency control is advantageous for effecting relatively great change in W_{OUT} with less change in W_{IN} and that the duty ratio control is advantageous for effecting relatively great change in W_{IN} with less change in W_{OUT} . Accordingly, it is possible to compensate for change in the chopper input power W_{IN} or the inverter output power W_{OUT} by suitably selecting the frequency control and/or the duty ratio control such that W_{IN} and W_{OUT} are kept at the same level while maintaining one of W_{IN} and W_{OUT} substantially unchanged. The above changes in W_{IN} and W_{OUT} are likely in the actual operational environment of the inverter AC power supply and are seen in the following situations, particularly when the power supply is used to drive the discharge lamp.

I Output power control:

When the power supply is designed to additionally include a dimmer for controlling light intensity, the inverter output power W_{out} has to be variable, thus inevitably breaking the relation $W_{in} = W_{out}$

5

II Differing operational modes:

When the power supply is designed to have $W_{in} = W_{out}$ at a certain frequency so as to provide a maintaining voltage for keeping the discharge lamp on (normal operational mode), it will have $W_{in} > W_{out}$ at the time of preheating the lamp by driving the switching elements at a greater frequency (preheating mode). And when the power supply is designed to have $W_{in} = W_{out}$ at the preheating mode, it will have $W_{in} < W_{out}$ at the normal operation mode.

10

III AC source voltage variations or fluctuations:

This eventually breaks the relation $W_{in} = W_{out}$.

20

IV Load variations:

When, for example, the power supply is utilized to drive a number of parallel coupled lamps, the inverter output power W_{out} will decrease upon one or more of the lamps becoming extinct or emission-less, resulting in $W_{in} > W_{out}$.

FIGS. 5 to 7 illustrate three possible situations having the relations between W_{in} and W_{out} with respect to switching frequency f and duty ratio D . In the figures, duty ratio D is determined in accordance with the above definition II-B. FIGS. 5A and 5B illustrates an ideal situation where W_{in} is kept equal to W_{out} at selected operating frequency f_1 and duty ratio d_1 so that the chopper can provide an optimum voltage to the inverter and distortion in the input current can be kept at a minimum.

FIGS. 6A and 6B illustrates an unbalanced situation where W_{out} becomes greater than W_{in} at the selected operation frequency f_1 and duty ratio d_1 so that input current will suffer from significant distortion to reduce the power factor.

FIGS. 7A and 7B illustrates another unbalanced situation where W_{in} becomes greater than W_{out} at the selected operation frequency f_1 and duty ratio d_1 so that the chopper will provide unduly high voltage which may damage the switching elements and the capacitors.

In order to balance W_{in} and W_{out} , it is possible to vary the switching frequency f [$f_1 \rightarrow f_2$] or duty ratio D [$d_1 \rightarrow d_2$]. In determining which of the switching frequency f and the duty ratio D is utilized, it is considered that which of W_{in} and W_{out} has to have less variation. That is, when compensating for the unbalanced conditions [$W_{in} < W_{out}$ of FIGS. 6A and 6B, $W_{in} > W_{out}$ of FIGS. 7A and 7B] while maintaining the variation in W_{in} to a less extent, the frequency control is preferable. Likewise, when compensating for the unbalanced conditions [$W_{in} < W_{out}$ of FIGS. 6A and 6B, $W_{in} > W_{out}$ of FIGS. 7A and 7B] while maintaining the resulting variation in W_{out} to a less extent, the duty ratio control is preferable.

In either case, both of W_{in} and W_{out} have to change from their initial level, although one of them could be maintained to see a relatively small variation. However, in the actual use of the inverter AC power supply, there is a certain requirement to maintain either of W_{in} and W_{out} at a fixed level when balancing them. Such requirement can be successfully satisfied by effecting a delicate control of combining the frequency control and the duty ratio control.

The above delicate combination control of frequency f and duty ratio D will be now discussed with regard to four possible conditions [A] to [D].

[A] For condition $W_{in} < W_{out}$ with $W_{in} = \text{fixed}$:

FIGS. 10A and 10B show a condition where $W_{in} < W_{out}$ at a selected operating frequency f_1 and a selected operating duty ratio d_1 . To compensate for this unbalanced condition or to have $W_{in} = W_{out}$, it is possible to raise frequency f [$f_1 \rightarrow f_2$] with fixed duty ratio $D = d_1$, or to raise duty ratio D [$d_1 \rightarrow d_2$] with fixed frequency $f = f_1$. In either of such frequency alone control or duty ratio alone control, both of W_{in}

and W_{out} will see certain changes, respectively. That is, the frequency alone control leads to the changes W_{in1} to W_{2f} [FIG. 10A] and W_{out1} to W_{2f} , and the duty ratio alone control leads to the changes W_{in1} to W_{2D} and W_{out1} to W_{2D} [FIG. 10B]. In order to maintain W_{in} fixed in obtaining the balanced condition, a combination control is made through the following steps:

- 5 1) Raising the frequency f_1 to a transient frequency f_3 so as to change W_{in} from point [a] to [g] on a curve $W_{in}[D = d_1]$ and to correspondingly change W_{out} from point [b] to [h] on a curve $W_{out}[D = d_1]$, at which condition the W_{in} is decreased to a less extent.
- 10 2) Raising the duty ratio D from d_1 to d_3 so as to change W_{in} from point [g] to [c] on a curve $W_{in}[f = f_3]$ and to correspondingly change W_{out} from point [h] to [c] on a curve $W_{out}[f = f_3]$, thus obtaining $W_{in} = W_{out}$ while maintaining W_{in} at an initial level W_{in1} .

[B] For condition $W_{in} < W_{out}$ with W_{out} = fixed:

15 FIGS. 11A and 11B show a condition where $W_{in} < W_{out}$ at selected operating frequency f_1 and duty ratio d_1 . In order to maintain W_{out} fixed in obtaining the balanced condition, a combination control is made through the following steps:

- 20 1) Raising the duty ratio D from d_1 to a transient duty ratio d_3 so as to change W_{in} from point [a] to [d] on a curve $W_{in}[f = f_1]$ and to correspondingly change W_{out} from point [b] to [e] on a curve $W_{out}[f = f_1]$, at which condition W_{out} is decreased to a less extent.
- 25 2) Lowering the frequency f_1 to a frequency f_3 so as to change W_{in} from point [d] to [c] on a curve $W_{in}[D = d_3]$ and to correspondingly change W_{out} from point [e] to [c] on a curve $W_{out}[D = d_3]$, thus obtaining $W_{in} = W_{out}$ while maintaining W_{out} at an initial level W_{out1} .

25 [C] For condition $W_{in} > W_{out}$ with W_{in} = fixed:

30 FIGS. 12A and 12B show a condition where $W_{in} > W_{out}$ at selected operating frequency f_1 and operating duty ratio d_1 . In order to maintain W_{in} fixed in obtaining the balanced condition, a combination control is made through the following steps:

- 35 1) Lowering the frequency f_1 to a transient frequency f_3 so as to change W_{in} from point [a] to [g] on a curve $W_{in}[D = d_1]$ and to correspondingly change W_{out} from point [b] to [h] on a curve $W_{out}[D = d_1]$, at which condition the W_{in} is increased to a less extent.
- 40 2) Lowering the duty ratio D from d_1 to d_3 so as to change W_{in} from point [g] to [c] on a curve $W_{in}[f = f_3]$ and to correspondingly change W_{out} from point [h] to [c] on a curve $W_{out}[f = f_3]$, thus obtaining $W_{in} = W_{out}$ while maintaining W_{in} at an initial level W_{in1} .

[D] For condition $W_{in} > W_{out}$ with W_{out} fixed:

40 FIGS. 13A and 13B show a condition where $W_{in} > W_{out}$ at selected operating frequency f_1 and duty ratio d_1 . In order to maintain W_{out} fixed in obtaining the balanced condition, a combination control is made through the following steps:

- 45 1) Lowering the duty ratio D from d_1 to a transient duty ratio d_3 so as to change W_{in} from point [a] to [d] on a curve $W_{in}[f = f_1]$ and to correspondingly change W_{out} from point [b] to [e] on a curve $W_{out}[f = f_1]$, at which condition W_{out} is decreased to a less extent.
- 50 2) Lowering the frequency f_1 to a frequency f_3 so as to change W_{in} from point [d] to [c] on a curve $W_{in}[D = d_3]$ and to correspondingly change W_{out} from point [e] to [c] on a curve $W_{out}[D = d_3]$, thus obtaining $W_{in} = W_{out}$ while maintaining W_{out} at an initial level W_{out1} . The above control modes are listed in the following table.

control mode	relation	condition required	switching frequency	duty ratio
[A]	$W_{IN} < W_{OUT}$	$W_{IN} = \text{fixed}$	$f \nearrow$	$D \nearrow$
[B]	$W_{IN} < W_{OUT}$	$W_{OUT} = \text{fixed}$	$f \searrow$	$D \nearrow$
[C]	$W_{IN} > W_{OUT}$	$W_{IN} = \text{fixed}$	$f \searrow$	$D \searrow$
[D]	$W_{IN} > W_{OUT}$	$W_{OUT} = \text{fixed}$	$f \searrow$	$D \searrow$

15

It is noted at this time that, although the frequency f and duty ratio D are controlled both in the lowering direction in the above control modes [C] and [D], there are certain differences in control amounts of lowering the frequency f and duty ratio D . That is, the frequency f and duty ratio D are controlled to see greater and smaller change, respectively in the control mode [C] of maintaining W_{IN} fixed than in the control mode [D] of maintaining W_{OUT} fixed. In the above controls, the duty ratio D is determined, in accordance with above definition II-B, to be a duty ratio of the switching element which turns to act for the chopper operation where the two switching elements are driven in such a manner that on-time of the one switching element corresponds to off-time of the other switching element. Thus defined ratio D can be therefore varied from 0 to 100%. However, when the duty ratio is to be adjusted only within a range below 50%, it is equally possible to control the duty ratio determined in accordance with the above definition II-A where the two switching elements are driven in such a manner as to have the same on-time period.

Although the above frequency and/or duty ratio control is found successful for positively balancing W_{IN} and W_{OUT} , there may be a case where more flexible control is required. To satisfy such requirement, it is contemplated in another version of the present invention to regulate the chopper input power W_{IN} over a wide range relatively independently of the control of the inverter output power W_{OUT} . This is achieved by controlling to intermittently cease the chopper operation for regulation of the chopper input power W_{IN} or the input power to the inverter, while leaving the inverter free to be controlled by the above frequency and/or duty ratio control for keeping the inverter output power W_{OUT} at a desired level. In order to intermittently cease the chopper operation while keeping the inverter operation, it is required to identify which of the two switching elements is currently responsible for the chopper operation and to stop operating only such switching element at suitable time intervals within each half cycle of the AC source voltage V_s . As discussed with reference FIGS. 3 and 4, the switching element responsible for the chopper operation is determined by the polarity of the AC voltage source V_s , i.e., switching element Q_1 in the positive half cycle and Q_2 in the negative half cycle of the AC voltage source V_s . To this end, a source voltage polarity detector is included to identify which of the two switching elements Q_1 and Q_2 is currently acting for the chopper operation such that the control is made to stop operating the switching element thus identified at suitable time intervals, thereby ceasing the chopper operation intermittently to regulate the resulting DC voltage supplied from the chopper to the inverter and therefore the input chopper power W_{IN} from the AC source voltage. With this control, therefore, W_{IN} can be regulated over a wide range by suitable selecting the time period in which the chopper operation is ceased and without causing a remarkable variation in the inverter output power W_{OUT} . Consequently, when combined with the previously mentioned frequency control which gives a larger variation in W_{OUT} with less variation in W_{IN} , the above control of intermittently ceasing the chopper operation is found most effective to regulate W_{IN} and W_{OUT} substantially independently.

It is therefore another object of the present invention to provide an inverter AC power supply which is capable of controlling the input power and the output power substantially independently.

In the meanwhile, for the inverter AC power supply circuit, it is desired to stop the chopper operation when a load is disconnected in order to prevent the chopper from continuously consuming the input power while there is no power consumption at the inverter, which would incur undue voltage increase at the input of the inverter or the capacitors C_2 and C_3 supplying the dc voltage to the inverter. Such undue voltage increase is very dangerous and will eventually break the capacitors C_2 and C_3 and the other circuit components including the switching elements Q_1 and Q_2 and diodes D_1 to D_4 . To prevent this potential hazard, a load detector is included to monitor whether the load is connected or disconnected such that the chopper can be disabled when no load condition is detected and be enabled when the load is again

connected. Although it is possible to deenergize the entire circuit of the chopper and the inverter upon detection of no load condition, the inverter is preferred to remain active so that it is capable of immediately providing a current when the load is again connected for detection of the on-load condition by the monitoring the current. Therefore, it is found effective to stop only the chopper while remaining the inverter active when the load is disconnected for preventing the undue voltage increase at the inverter input and at the same time for easy detection of the re-connected load condition by the use of the inverter output. For selectively stop operating the chopper in the above mentioned circuit, one of the switching elements Q_1 and Q_2 currently acting for the chopper can be identified by monitoring the polarity of the input AC voltage V_s as explained previously so that thus identified switching element is controlled to turn off over the entire half cycle of the input AC voltage V_s , thereby generating no additional DC voltage to the input of the inverter or the capacitors C_2 and C_3 while the other switching element is kept active for the inverter operation.

Further, in the case of driving discharge lamps with the above inverter AC power supply, it is preferred to provide a lamp current have less high frequency components which may cause acoustic resonance leading to unstable discharge arcs, flickering or even to extinction of the lamp. For obtaining the lamp current with reduced high frequency components, the inverter AC power supply of the present invention is cooperative with an inductor connected in series with the lamp and a bypass capacitor connected across the lamp and is controlled in such a manner as to stop driving for a suitable time period one of the switching elements currently acting only for the inverter operation and not for the chopper operation while keeping the other switching element active. With this control, there is a certain period in which only one of the switching elements responsible for the chopper and inverter operations is active while the other switching element is kept non-conductive. During this period, the one active switching element will pass a current from the output DC voltage of the chopper in one direction through a parallel circuit of the lamp and the bypass capacitor each time it is turned on, and the inductor in series with the lamp acts to continuously flow a current in the same direction through the parallel circuit of the lamp and the bypass capacitor each time the active switching element is turned off. At this occurrence, the bypass capacitor acts to pass high frequency components resulting from the high frequency drive of the switching element, permitting the lamp to see the lamp current substantially free from such high frequency component, whereby preventing the occurrence of the undesirable acoustic resonance. Since the active switching element responsible for the chopper and inverter operations will change between two switching elements Q_1 and Q_2 in synchronism with the polarity reversal of the input AC source voltage, the lamp current is defined as a current having a generally rectangular waveform which is removed of the high frequency components and alternates at a low frequency approximately corresponding to the frequency of the input AC source voltage. Whereby the discharge lamp can be driven by the low frequency ac voltage in a stable manner without causing the harmful acoustic resonance by the use of the above inverter AC power supply.

Although the above scheme of disabling one of the switching elements responsible for the inverter only operation while keeping the other switching element responsible for the chopper and inverter operations active is discussed for driving the discharge lamp, it should not be limited thereto and may be adapted to provide a low frequency AC voltage of rather rectangular waveform.

The above and still other advantageous features of the present invention will become more apparent from the following description of the preferred embodiments when taken in conjunction with the attached drawings.

10

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring now to FIG. 14, an inverter AC power supply is shown in a general arrangement for easy
 15 understanding of the present invention. The power supply comprises a chopper 1 and an inverter 2. The
 chopper 1 receives a low frequency AC voltage from a commercial voltage source V_s and acts to switch
 the voltage at a high frequency for providing a smoothed DC voltage to a capacitor C. The inverter 2
 received the smoothed DC voltage from the capacitor C to switch the same to provide a high frequency AC
 voltage to a load L. An input power sensor 11 is provided between the chopper and the voltage source V_s
 to monitor an input power W_{IN} supplied to the chopper 1. Likewise, an output power sensor 12 is provided
 20 between the inverter 2 and the load L to monitor an output power W_{OUT} being supplied from the inverter 2.
 A power controller 10 is connected to the sensors 11 and 12 in order to control, based upon the monitored
 results, the switching of the inverter and the chopper for equalizing the chopper input power W_{IN} and the
 inverter output power W_{OUT} .

25

First embodiment <FIGS. 12 to 17>

FIG. 15 shows a circuit of the power supply in accordance with a first preferred embodiment. The circuit
 30 configuration is identical except for the power controller 10 to those of FIG. 1 which is explained in the
 summary of the invention. The basic operation of the circuit is also identical to the circuit of FIG. 1.
 Therefore, no further explanation is deemed unnecessary for the basic circuit arrangement and operation.
 However, it appears important here to repeat the features of the circuit that:

- 1) An inductor L_2 is inserted in series with the AC voltage source V_s across the rectifier input so as
 35 to counteract the captive reactance of capacitors C_1 and C_2 for improving the power factor;
- 2) The chopper 1 and the inverter 2 shares switching transistors Q_1 and Q_2 for effecting the chopper
 and the inverter operations;
- 3) During the positive half cycle of the input AC source voltage, Q_1 is responsible for both of the
 40 chopper and inverter operations, while Q_2 is responsible only for the inverter operation, as shown in FIGS.
 3A to 3D; and
- 4) During the negative half cycle of the input AC source voltage, Q_2 is responsible for both of the
 45 chopper and inverter operations, while Q_1 is responsible only for the inverter operation, as shown in FIGS.
 4A to 4D. In addition, a low pass filter 3 is provided between the AC voltage source V_s and the chopper 1
 in order to obtain an input current I_{IN} to the power supply circuit which is free from being influenced by the
 50 high frequency switching operation and therefore can retain a continuous wave form with less distortion. In
 the circuit of FIG. 12, the switching elements are bipolar transistors Q_1 and Q_2 operating a frequency range
 around 40 KHz and the load is shown to comprise a series combination of an inductor L_3 and discharge
 lamp FL [FCL-32EX/30 by Matsushita Denshi Kogyo, Japan] with a preheating capacitor C_4 . Capacitor C_4 is
 55 connected across filaments of the lamp FL to form a series resonant circuit with inductor L_3 for preheating
 the filaments at the start of energizing the lamp FL. The circuit is designed, for example, to have $L_2 = 0.95$
 mH, $L_3 = 1.02$ mH, $C_2 = 100 \mu F$ so as to obtain an inverter input of 260V from the commercial AC
 voltage of 100V and generate a lamp current of 350 mA when driving Q_1 and Q_2 at a switching frequency f
 = 40 KHz and at a duty ratio $D = 35\%$. The duty ratio D is determined in accordance with the above
 definition II-B explained previously in the summary of the invention.
- 55 For determination of the chopper input power W_{IN} , the input power sensor 11 may be configured, for
 example,
 - 1) to multiply the input voltage by the input current;
 - 2) to analyze and process the waveform of a current flowing into L_2 ; or

3) to process a current flowing into Q_1 and Q_2 . And, for determination of the inverter output power W_{out} , the output power sensor 12 may be configured, for example,

- 1) to multiply a load current flowing to the load and a load voltage developed across the load;
- 2) to calculate only from the load current;

5 3) to calculate only from the load voltage; or

4) to process a current flowing into Q_1 and Q_2 . In any case, it is required to determine W_{in} and W_{out} averaged over at least one complete cycle of the input AC voltage.

Operation of the power controller 10 will be now discussed with regard to the following operating conditions where undesirable unbalancing of W_{in} and W_{out} takes place.

10

I. Light intensity control [Dimmer control]

15

Raising light intensity:

Starting from a balanced condition $W_{in} = W_{out}$ at initially selected frequency $f (=f_0)$ and duty ratio $D = D_0$, as shown in FIGS. 5A and 5B, when the switching frequency f is decreased so as to correspondingly increase the light intensity or W_{out} , there occurs an unbalanced condition $W_{out} > W_{in}$ since W_{out} shows a gradient greater than W_{in} with the frequency decrease in an operational range from f_0 , as shown in FIG. 6A, where the switching frequency is shown as decreased from f_0 to f_1 . Upon occurrence of this unbalanced condition, the power controller 10 responds immediately to control Q_1 and Q_2 to reestablish a balanced condition $W_{in} = W_{out}$ while keeping W_{out} fixed at the raised level, in accordance with the control mode [B] discussed previously with reference to FIGS. 11A and 11B. That is, the control is made by firstly increasing the duty ratio D [$d_1 \rightarrow d_3$] and then slightly decreasing the switching frequency f [$f_1 \rightarrow f_3$].

Lowering light intensity:

30

When, on the other hand, the switching frequency f is increased in order to correspondingly lower the light intensity or W_{out} from the above starting condition of FIGS. 5A and 5B, there occurs another unbalanced condition $W_{in} > W_{out}$ since W_{in} shows a gradient greater than W_{in} with the frequency increase in an operational range from f_0 , as shown in FIG. 7A, where the switching frequency is shown as increased from f_0 to f_1 . Upon occurrence of this unbalanced condition, the power controller 10 responds immediately to control Q_1 and Q_2 to reestablish a balanced condition $W_{in} = W_{out}$ while keeping W_{out} fixed at the lowered level, in accordance with the control mode [D] discussed previously with reference to FIGS. 13A and 13B. That is, the control is made by firstly decreasing the duty ratio D [$d_1 \rightarrow d_3$] and then slightly decreasing the switching frequency f [$f_1 \rightarrow f_3$].

II. Differing lamp operating modes

45

W_{in} and W_{out} set balanced at a lamp-on mode:

For the power supply which is designed to have $W_{in} = W_{out}$ at a certain frequency f_1 so as to provide a maintaining voltage for keeping the lamp on, as shown in FIG. 16, it is required at the start of igniting the lamp to drive Q_1 and Q_2 at a higher frequency f_4 in order to allow capacitor C_4 to pass a preheating current through lamp filaments from the inverter output for preheating the filaments. After the filaments are sufficiently heated, then the switching frequency is lowered to f_1 to develop a high voltage (gas breakdown voltage) across capacitor C_4 , thereby turning on the lamp. As apparent from FIG. 16, at the time of preheating the filament with an increased switching frequency f_4 , W_{out} sees a greater change than W_{in} thus causing an unbalanced condition $W_{in} > W_{out}$. When such condition continues to consume a greater W_{in} at the chopper than W_{out} at the inverter output, an unduly high voltage will develop at capacitor C_2 and C_3 and eventually break them. To avoid or compensate for this unbalanced condition at the preheating

frequency f_4 , the power controller 10 responds immediately to control Q_1 and Q_2 to have $W_{IN} = W_{OUT}$ while keeping W_{OUT} fixed at the lowered level, in accordance with the control mode [D] discussed previously with reference to FIGS. 13A and 13B.

5

W_{IN} and W_{OUT} set balanced at a preheating mode:

On the contrary, when the power supply which is designed to have $W_{IN} = W_{OUT}$ at a preheating frequency f_4 , it will have an unbalanced condition $W_{IN} < W_{OUT}$ in a normal lamp-on operation at a switching frequency f_1 ($< f_4$). To reestablish the balanced condition $W_{IN} = W_{OUT}$, the control is made at the power controller 10 to increase W_{IN} without substantially changing W_{OUT} in accordance with the control mode [B] discussed previously with reference to FIGS. 11A and 11B.

15

III AC source voltage variations or fluctuations:

Raising in AC source voltage

20

When by some reason the AC source voltage is raised from a rated voltage to cause an unbalanced condition $W_{IN} > W_{OUT}$ at the selected frequency f_1 and D_1 , the power controller 10 operates, in accordance with the above control mode [B] of FIGS. 11A and 11B, to compensate for such variation, thus obtaining the balanced condition $W_{IN} = W_{OUT}$ without keeping W_{OUT} substantially at a desired level.

Lowering in AC source voltage

30

When, on the other hand, the AC source voltage is lowered from a rated voltage to cause an unbalanced condition $W_{IN} < W_{OUT}$ at the selected frequency f_1 and D_1 , the power controller 10 operates, in accordance with the above control mode [D] of FIGS. 13A and 13B, to compensate for such variation, thus obtaining the balanced condition $W_{IN} = W_{OUT}$ without keeping W_{OUT} substantially at a desired level.

35

IV Load variations:

When the power supply is utilized to drive a number of parallel coupled lamps FL_1 to FL_3 , as shown in FIG. 17, W_{IN} may vary depending upon the load conditions. For instance, when any one of the lamps becomes extinct due to filament breakage or lamp disconnection, the inverter output W_{OUT} will be correspondingly decreased while the chopper input is still maintained at a constant W_{IN} determined at selected frequency f_1 and duty ratio D_1 , leading to an unbalanced condition $W_{IN} > W_{OUT}$ which would give unduly high voltage stress to capacitor C_2 and C_3 , switching transistors Q_1 and Q_2 . That is, with the illustrated load configuration having individual resonant circuits for the fluorescent lamps FL_1 to FL_3 , even when one of the lamps FL_1 to FL_3 become extinct, the output power of the other two lamps are kept substantially unchanged so that the inverter output power W_{OUT} is reduced to two-thirds (2/3) of the initial power. For the multi-lamp driving operation, it is in most cases required to keep the overall output power constant even when one of the lamps becomes extinct. Therefore, it is preferred to reestablish the balanced condition $W_{IN} = W_{OUT}$ without causing substantial change in W_{OUT} . Such control can be successfully made at the power controller 10 in accordance with the above control mode [D] of FIGS. 13A and 13B.

Although, in the above embodiment, the control is made by constantly monitoring W_{IN} and W_{OUT} by obtaining input and output currents or voltages, it is equally possible to monitor harmonics superimposed in the input current as a parameter representative of the relation between W_{IN} and W_{OUT} and to control to keep the monitored harmonic level below a suitable threshold for maintaining the relation W_{IN} and W_{OUT} .

Referring to FIG. 18, a power supply in accordance with a second embodiment of the present is shown to additionally include a source voltage polarity detector 20 which provides an output indicating of the 5 polarity of the AC source voltage V_s to the power controller 10. The other circuit arrangement is identical to the above first embodiment except that MOSFET (Metal Oxide Semiconductor Field Effect Transistor) is utilized as first and second switching transistors Q_1 and Q_2 . In this circuit, parasitic diodes intrinsic to MOSFETs are best utilized to form the first and second diode D_1 and D_2 for reducing the number of components of the circuit.

This embodiment is contemplated to regulate the chopper input power W_{IN} over a relatively wide range while causing less influence on the inverter output power W_{OUT} by ceasing the chopper operation for a suitable time period while substantially keeping the inverter operation. In other words, one of the switching transistors Q_1 and Q_2 which is responsible for the chopper operation is periodically ceased or kept turned off while the other switching transistor is being kept to turn on and off. As previously discussed with 10 reference to FIGS. 3 and 4, it is known that Q_1 is responsible for the chopper operation and Q_2 is responsible for the inverter operation during the positive half cycle of the AC source voltage V_s , and vice versa during the negative half cycle of the AC source voltage V_s . In this manner, the switching element responsible for the chopper operation will change between Q_1 and Q_2 in exact synchronism with the 15 polarity reversal of the AC source voltage and therefore can be identified by the output of the polarity detector 20. Therefore, the power controller 10 can control to intermittently cease the chopper operation by selectively disabling one of the switching transistors Q_1 and Q_2 thus identified to be responsible for the chopper operation. As shown in FIG. 19, Q_1 and Q_2 are controlled to intermittently disabled for a suitable 20 time interval in order to reduce W_{IN} to a desired extent while keeping the resulting variation in the inverter output power W_{OUT} at a minimum. That is, when Q_1 is disabled, for example, during the positive half cycle of the AC source voltage V_s , the inverter output current I_{LA} is also ceased due to the fact that Q_1 is also 25 responsible for the inverter operation. However, at this occurrence, Q_2 is still operating to effect the inverter operation such that the instantaneous inverter output power is reduced to one half only temporarily during the limited short interval where Q_1 is off, and therefore W_{IN} can see only a less reduction over the half cycle of the AC source voltage V_s . In FIG. 19, I_{CH} and I_{IN} represent a chopped current and an input current to the chopper, respectively. Accordingly, it is found effective to use this control for compensation of the 30 unbalanced condition $W_{IN} > W_{OUT}$ with less attendant variation in W_{OUT} . For example, this control is found particularly suitable to compensate for the unbalanced condition $W_{IN} > W_{OUT}$ which occurs at the time of lowering the light intensity, as described with reference to the first embodiment. That is, by intermittently ceasing the chopper operation for a suitable off time interval T_{OFF} within each half cycle of the input AC 35 source voltage V_s , as shown in FIG. 19, the chopper input power W_{IN} can be reduced to reestablish the balanced condition $W_{IN} = W_{OUT}$ also at the increased switching frequency without substantially causing the variation in W_{OUT} . It is noted at this time that, as shown in FIG. 19, when the off time interval T_{OFF} are set to be evenly distributed over each half cycle of the input AC source voltage V_s , it is possible to obtain an 40 input current I_{IN} having a waveform analogous to that of the input voltage V_s , thereby reducing harmonics as much as possible and therefore maintaining an improved power factor. Although W_{IN} can be controlled over a wide range by suitably varying the off time interval for ceasing the chopper operation, the off time interval should be selected in association with the design of the low pass filter 3 in order to avoid remarkable harmonics superposed in the input current which would otherwise lower the power factor.

Further, when the above control is combined with the previously mentioned frequency control having 45 inherent characteristic of obtaining a greater change in W_{OUT} with less change in W_{IN} , it is possible to vary the W_{IN} and W_{OUT} substantially independently, enabling a delicate control for equalizing W_{IN} and W_{OUT} .

FIG. 20 shows a circuit which form a portion of the power controller 10 to effect the above control of intermittently ceasing the chopper operation. The circuit includes an oscillator 30, a calibrator 31, and a switch driver 32. The oscillator 30 is of general configuration generating first and second oscillatory outputs 50 OUT_1 and OUT_2 , as shown in FIG. 21, which are fed to the calibrator 32 together with a polarity signal SGN issued from the above source voltage polarity detector 20. The first oscillatory output OUT_1 and the polarity signal SGN are input through an AND-gate G_1 to a mono-stable multivibrator MV_1 , such that MV_1 is triggered to produce a signal P_1 at a trailing edge of the first oscillatory output OUT_1 when SGN is high or the input AC voltage V_s is positive. The signal P_1 , which is set to have a predetermined width normally 55 several times greater than that of the switching cycle, is then fed to a mono-stable multivibrator MV_2 to trigger the same for producing a signal P_2 having the pulse width greater than that of OUT_1 . The signal P_2 is fed together with the polarity signal SGN to an AND-gate G_2 of which output is inverted at a NOT gate G_3 and is then fed to an AND-gate G_4 together with the first oscillatory signal OUT_1 so that AND-gate G_4

provides a driving signal DR_1 for driving the switching transistor Q_1 . In this manner, during the positive half cycle of V_s , multivibrator MV_2 generates at a regular interval determined by multivibrator MV_1 the signal P_2 which negates a portion of the first oscillatory output OUT_1 at that interval for obtaining a resulting first drive signal DR_1 , thus enabling to periodically cease the chopper operation. While, on the other hand, during the negative half cycle of the input AC source voltage V_s , the polarity signal SGN is inverted at NOT gates G_6 and G_7 , respectively and is fed together with the second oscillatory output OUT_2 to the like logic circuit so as to trigger a mono-stable multivibrator MV_4 at a regular interval determined by a mono-stable multivibrator MV_3 for generating a signal P_4 which negates the second oscillatory output OUT_2 and providing through an AND gate G_{10} a second drive signal DR_2 for driving the switching transistor Q_2 , thus enabling to periodically cease the chopper operation during the negative half cycle.

FIG. 22 shows a circuit diagram which is common to the multivibrators MV_1 to MV_4 utilized in the above logic. A timer IC [NE555, by Signetics] is included to receive an input at a trigger terminal [pin no.2] through a differential circuit of resistors R_{11} and R_{12} and capacitor C_{11} such that the trigger terminal [pin no. 2] sees a voltage decrease as the input decrease. When the voltage at the trigger terminal is decreased below 1/3 of a control voltage Vcc applied between a power terminal [pin no.8] and a ground terminal [pin no.1], an output terminal [pin no.3] is triggered to provide a High-level signal and at the same time to make a discharge terminal [pin no.7] into a high impedance state. Also, when a threshold terminal [pin no.6] sees a voltage decrease down to below 2/3 of Vcc , the power terminal [pin no.3] provides a Low-level signal and at the same time the discharge terminal [pin no.7] goes "High". A reset terminal [pin no.4] is connected to the power terminal [pin no.8] and a frequency control terminal [pin no.5] is connected to the ground terminal [pin no.1] through a decoupling capacitor C_{13} . The control voltage Vcc is applied to a series circuit of a resistor R_{13} and a capacitor C_{12} which is coupled to the threshold terminal [pin no.6] and to the discharge terminal [pin no.7] at the connection between R_{13} and C_{12} and forms a time constant circuit for the timer IC, thus operating the timer IC as the mono-stable multivibrator. That is, when the trigger terminal [pin no.2] goes "Low-level", the output terminal [pin no.3] is triggered to provide "High-level" signal for a time period determined by C_{12} and R_{13} or until a voltage at the threshold terminal [pin no.6] is dropped to a threshold voltage ($= 2/3 Vcc$), during which period the High-level signal at the output terminal is maintained until a voltage at capacitor C_{12} reaches the threshold voltage even when the input terminal (pin no.2) see a voltage change. It is noted at this time that a time constant of C_{12} and R_{13} is set to be greater for the multivibrators MV_1 and MV_3 than for MV_2 and MV_4 so as to obtain the output signals P_1 to P_4 of differing pulse widths, as seen in FIG. 21.

Although the above control scheme of intermittently ceasing the chopper operation is described with reference to the chopper-and-inverter circuit of FIG. 18, it is of course applicable to like circuits, as illustrated in FIGS. 23A to 23D, which have different connection points [A] and [B] between the chopper and the AC voltage supply, and also to a circuit of FIG. 24 in which another pair of switching transistors Q_3 and Q_4 is added to form an inverter of full-bridge configuration with Q_1 and Q_4 , and in which a smoothing capacitor C_0 is connected across Q_3 and Q_4 to provide an DC voltage to the inverter. In the circuit of FIG. 24, Q_3 and Q_4 are driven in synchronism respectively with Q_2 and Q_1 by the same drive signals S_2 and S_1 to effect the same operation as in the circuit of FIG. 18 except that the inverter produces an output voltage of a level approximately twice that of the circuit of FIG. 18.

Further, the above control is also found effective to drive an incandescent lamp LA with the like inverter and chopper circuit, as shown in FIG. 25. In this operation mode, the inverter provides to the incandescent lamp a lamp current I_{LA} having a rectangular waveform, as shown in FIG. 26 since there is no resonance circuit in the load. For effecting a dimmer control of the lamp LA , it is found effective to use the above control of intermittently ceasing the chopper operation in place of controlling the switching frequency since the frequency control has no effect on the lamp current I_{LA} for the incandescent lamp LA . That is, when the lamp LA is required to be dimmed, for example, from a max light intensity condition as shown in the upper part of FIG. 26, one of the switching transistors Q_1 and Q_2 responsible for the chopper operation is controlled to be intermittently disabled, as shown in the lower part of FIG. 26, so as to reduce an input current to the chopper or the chopper input power W_{IN} , thereby correspondingly reducing a DC voltage developed at capacitors C_2 and C_3 . Therefore, the input power to the inverter is also decreased to correspondingly reduce the inverter output power W_{OUT} or the light intensity as desired. Thus, the dimmer control for the incandescent lamp LA can be successfully in the power supply of the present Invention by controlling to intermittently cease the chopper operation. It is noted at this time that W_{IN} and W_{OUT} can be substantially balanced in this dimmer control with or without the control of the duty ratio.

Furthermore, to drive the incandescent lamp LA with the circuit of FIG. 25, it is also possible to control Q_1 and Q_2 in a manner, as shown in the upper part of FIG. 27, to operate only Q_1 during the positive half cycle of the input AC source voltage V_{IN} and only Q_2 during the negative half cycle of V_{IN} . In this mode, the

power circuit provides a lamp current I_{LA} in the form of repeating pulses of which polarity is reversed in synchronism with the polarity reversal of V_{IN} such that lamp current I_{LA} has an effective value which is one half of the peak value. So long as the input AC source voltage V_{IN} is maintained at a fixed level, the power supply operates in the manner, as shown in the upper part of FIG. 27 to drive the lamp LA appropriately while maintaining a balanced condition $W_{IN} = W_{out}$. When by some reason the AC source voltage is increased, a control can be made, as shown in the lower part of FIG. 27, to intermittently disable Q_1 and Q_2 respectively in the positive and negative half cycles of V_{IN} so as to compensate for the input AC voltage increase and keep the input power W_{IN} at a fixed level irrespective of the input AC voltage increase. During this control of reducing the input power, it is also controlled, as shown in the lower part of FIG. 27, to turn on Q_2 immediately after Q_1 is turned off within the positive half cycle of V_{IN} and to likewise turn on Q_2 immediately after Q_2 is turned off within the negative half cycle of V_{IN} , whereby maintaining the effective value of the lamp current I_{LA} to be one half of the peak value and therefore maintaining the inverter output power W_{out} constant at a desired level. With this consequence, the output power or the light intensity of the lamp can be kept free from the variation possible in the input AC source voltage.

15

Third embodiment <FIGS. 28 to 46>

An third embodiment of the present invention is contemplated to additionally include means to cease only the chopper operation when the load is disconnected in order to avoid undue voltage increase or power consumption at the chopper which would lead to the breakage of the circuit components, particularly the switching transistors and the capacitors which store input energy and provide the inverter input. As shown in FIG. 28[22], an inverter AC power supply in accordance with the present embodiment includes, in addition to the like chopper and inverter circuit as discussed in the previous embodiments, an off-load detector 40 for detecting an off-load condition, a like source voltage polarity detector 20 as utilized in the second embodiment, and a controller 50. Although the controller 50 effects the above power control of balancing W_{IN} and W_{out} in cooperation with an input power monitor and an output power monitor as discussed in the first embodiment, duplicate explanation of such power control is avoided in the following description and drawings. The controller 50 is configured in the present embodiment to control the switching transistors Q_1 and Q_2 in accordance with detected results from detectors 20 and 40 so as to disable the chopper operation so long as the load L is disconnected, yet keeping the inverter operation to make the inverter ready for providing a load current as soon as the load is disconnected. With this consequence, it is readily possible to detect the re-connection of the load by monitoring such load current to thereby facilitate the design of restarting the load. As previously discussed, Q_1 and Q_2 in the chopper/inverter circuit of FIG. 28 can be identified by the polarity sensor 20 as to whether or not they are currently responsible for the chopper operation. Accordingly, the controller 50 can, in response to the outputs from the individual detectors 20 and 40, control to disable Q_1 in the positive half cycle and Q_2 in the negative half cycle of the input AC source voltage V_{IN} for disabling the chopper operation while allowing the inverter operation. In detail, the polarity detector 20 is configured to provide a polarity signal SGN which goes "High" when $V_{IN} > 0$ and goes "Low" when $V_{IN} < 0$. The off-load detector 40 is also configured to provide a load signal NL which goes "High" when no load condition is detected and otherwise remains "Low". The controller 50 include a logic, as shown in FIG. 29, in which S_1 and S_2 are drive signals generated from an oscillator (not shown) provided in the controller 50 to drive Q_1 and Q_2 , respectively. In operation, when the load signal NL is low as indicative of that the load is connected, OR-gates G_3 and G_4 are both operative to provide "High-level" output such that AND-gates G_5 and G_6 are both enabled to pass the drive signals S_1 and S_2 , irrespective of the polarity signal SGN, whereby maintaining the normal operation of effecting the chopper and inverter operations. When the load signal NL goes "High-level" as indicative of that the load is disconnected, OR-gates G_3 and G_4 will be made in the same condition as AND-gates G_1 and G_2 to effect the followings:

- 1) When the polarity signal SGN is "High" as indicative of $V_{IN} > 0$, AND-gate G_2 goes "High" to thereby provide S_2 from AND-gate G_6 for enabling to turn on and off Q_2 or keeping the inverter operation. At this condition, however, AND-gate G_1 goes "Low" to render AND-gate G_5 "Low", ceasing to provide S_1 and therefore disabling the chopper operation; and
- 2) When SGN goes "Low" as indicative of $V_{IN} < 0$, AND-gate G_1 turns to have "High-level" output to thereby allow AND-gate G_5 to output S_1 for enabling the inverter operation. At this condition, AND-gate G_2 goes "Low" to thereby keep the output of AND-gate G_6 "Low", thus inhibiting to provide S_2 to Q_2 and therefore disabling the chopper operation. The above control scheme is seen in FIG. 30 in terms of

waveforms at the individual outputs, from which it can be confirmed that so long as the load signal NL remains "Low", S₁ and S₂ are generated to effect the chopper and inverter operations irrespective of the polarity signal SGN level, and that after NL goes high (at time t₀) the output of S₁ is inhibited when SGN is "High" and the output of S₂ is inhibited when SGN is "Low". In the figure, S₁ and S₂ are depicted to have a relatively long cycle for illustration purpose only, but are in fact to have a much shorter cycle than illustrated.

The polarity detector 20 is coupled to the chopper/inverter circuit to detect the instantaneous polarity of the input AC voltage by monitoring currents or voltages at suitable points which may include, for example, points designated in FIG. 31 at:

- 10 (a) for input AC current;
- (b) for input AC voltage;
- (c) for chopper current;
- (d) for voltage at inductor L₂ for chopper operation by means of an additional secondary winding, for instance;
- 15 (e),(e') for current through D₄ or D₃;
- (f),(f') for voltage across D₄ or D₃;
- (g),(g') for current through Q₂ or Q₁;
- (h),(h') for voltage across Q₂ or Q₁; and
- (i),(i') for load current within the inverter circuit. The points (a),(c),(e),(e'),(g),(g'),(i),(i') are for 20 monitoring the currents which are not present in the off-load condition, and are therefore found only effective to detect an on-load condition and not the off-load condition. Also point (d) is found only effective only in the on-load condition and not in the off-load condition, since the intended voltage will not develop across L₂ in the absence of a current therethrough. While, on the other hand, (h),(h') is found effective in 25 the off-load condition but not in the on-load condition since the voltage across Q₁ or Q₂ will change depending upon the polarity of the input AC voltage at the off-load condition but will be of rectangular wave synchronized with the drive signal S₁ or S₂ having no relation to the polarity of the input AC voltage. With this consequence, Therefore, points (b), (e), or (e') is found suitable to monitor the polarity both in the off-load and on-load conditions, although it may of course possible to use different points for monitoring the polarity separately in the on-load condition and in the off load condition.
- 30 The off-load detector 40 is coupled to the chopper/inverter circuit or the load by monitoring currents or voltages at suitable points which may include, for example, points illustrated in FIG. 32A and 32B at:
 - (j),(j') for current through Q₂ or Q₁;
 - (k),(k') for voltage across Q₂ or Q₁;
 - (l) for load current on the load side;
 - 35 (m),(m') for load current within the inverter;
 - (n) for current through C₃;
 - (o) for voltage across C₂ and C₃;
 - (p) for voltage across L₃ in the load circuit through additional secondary winding; and
 - (q) for voltage at one end of lamp FL. The above points are effective to detect not only the off-load 40 condition but also the on-load condition. This is because that even after the chopper operation is suspended in response to the off-load detection, the inverter operation is controlled to be still operating such that, as soon as the load is reconnected, the inverter can immediately provide through the active one of Q₁ and Q₂, the load and C₂ and C₃ a load current with a corresponding voltage change by which the on-load condition can be detected. Although the above points are effective for monitoring both the off-load and on load 45 condition, the off-load condition alone may be detected by the use of a thermo-sensor monitoring a temperature of the load or switching elements or by the use of an optical sensor monitoring a light energy from the lamp FL in case it is connected as the load.

FIG. 33 illustrates one example for detecting the source voltage polarity and the off-load condition in the above chopper/inverter circuit. The polarity is detected by monitoring a voltage across diode D₄ at [J] by 50 the use of a voltage divider of R₁ and R₂, and the off-load condition is detected by monitoring a load current at [X-Y] by the use of a current transformer CT inserted in series with the load between the inverter output ends A and B. When the load is disconnected to open the inverter outputs ends A and B, a voltage [X-Y] at a secondary winding of CT is decreased to zero for indicate the off-load condition. At this off-load condition, Q₁ and Q₂ are controlled to be selectively disabled depending upon the Input AC source voltage 55 polarity detected at [J] (Q₁ while V_{IN} > 0, Q₂ while V_{IN} < 0) for ceasing the chopper operation while keeping the inverter operation, as discussed hereinbefore. When the load is reconnected, the load current is caused to flow between the inverter output ends A and B from either of C₂ or C₃, providing a corresponding voltage at [X-Y] to thereby enabling the detection of the on-load condition and restart of the circuit in a

suitable manner.

FIG. 34 illustrates one example of the source voltage polarity detector 20 for use with the circuit of FIG. 33. The detector 20 has inputs connected to points [J] and [G] in the circuit of FIG. 33 and includes a capacitor C_7 . When the source voltage $V_{IN} > 0$, diode D_4 sees a high reverse bias which is divided by resistors R_1 and R_2 to provide at [J] a corresponding voltage by which capacitor C_7 is charged to a certain level above a reference voltage determined by resistors R_5 and R_6 such that a comparator CP_1 outputs the "High-level" polarity signal SGN. When, on the other hand, $V_{IN} < 0$, diode D_4 sees a small forward bias so that capacitor C_7 is discharged to have a corresponding voltage level at the input of comparator CP_1 lower than the reference voltage, whereby the "Low-level" polarity signal SGN is output from comparator CP_1 .

FIG. 35 illustrates one example of the off-load detector 40 adapted in use to the above circuit of FIG. 33. During the on-load condition, the current transformer CT generates between points [X-Y] an alternating voltage which is applied through a diode bridge rectifier DB to charge a capacitor C_6 to a level higher than a reference voltage determined by resistors R_3 and R_4 such that a comparator CP_2 provides the "Low-level" load signal NL. Upon the off-load condition, no voltage is developed between [X-Y] and therefore that no current is supplied to capacitor C_6 so that capacitor C_6 will be discharged down below the reference voltage, whereby comparator CP_2 turns to output the "High-level" load signal NL. To expedite the discharging of C_6 at the off-load condition, C_6 may be connected in parallel with additional discharging capacitor or may have less capacitance.

FIG. 36 illustrates another preferred set of points for detection of the source voltage polarity and the off-load condition in the like chopper/inverter circuit when the circuit is used for driving the load including a series resonance circuit of an inductor L_3 and a capacitor C_5 connected in parallel with the lamp FL. In this modification, the voltage polarity is detected by monitoring input AC voltage V_{IN} between points [M-N], while the off-load condition is detected by monitoring a current through Q_1 by the use of a current transformer CT as well as by monitoring a current through Q_2 by a resistor R_0 . When the lamp FL is disconnected as indicated in the figure, although a current will flow through the series resonance circuit of L_3 and C_4 between the inverter output ends A and B, such resonance current is substantially a reactive current hardly consuming the output power, thus causing also the off-load condition. However, as seen from FIG. 37 illustrating waveforms for input AC voltage V_{IN} , current it through inductor L_3 , voltage V_{CS} at capacitor C_5 , the circuit of FIG. 36 will see a current for a short time interval each time the voltage polarity is reversed, which invalidates to detect reconnection of the load simply by monitoring the current through the switching transistors. To avoid this inconvenience and assure reliable reconnected load detection, it is preferred either to stop the detection for a time interval in which such current continues or to average such current over an extended period for valid comparison with a reference value.

FIG. 38 shows one example of the source voltage polarity detector 20 in which the input AC voltage V_{IN} received at terminals [M-N] is step down at a transformer Tf and is rectified by diode D_5 to provide at resistor R_7 a corresponding voltage V_R which is to be compared at a comparator CP_1 with a reference voltage determined by resistors R_5 and R_6 . When $V_{IN} > 0$, a high voltage V_R is developed at R_7 which is greater than the reference voltage so that CP_1 outputs the "High-level" polarity signal SGN. When $V_{IN} < 0$, no voltage is developed at R_7 so that CP_1 outputs the "Low-level" polarity signal SGN. It is noted at this time that, although the reference voltage is required to be as low as possible in the sense of balancing the "High-level" period and the "Low-level" period of the polarity signal SGN, it is preferably set to be a certain high level enough for discriminating a possible noise in the detector and therefore assuring a reliable detection, since a noise voltage at R_7 might cause CP_1 to erroneously output the "High level" signal SGN.

FIG. 39 illustrates one example of the off-load detector 40 utilized in the circuit of FIG. 36. While the load is connected to flow a current through transistor Q_1 (or diode D_1), the current transformer CT generates between a point [X] and a ground [G] an alternating voltage which is applied as being rectified by a diode D_7 to charge a capacitor C_8 to a level higher than a reference voltage determined by resistors R_9 and R_{10} such that a comparator CP_3 provides a "High-level" output. Also in the on-load condition, transistor Q_2 (or diode d_2) sees a current which provides a corresponding AC voltage between a point [K] and the ground [G] which voltage is then rectified through diode D_6 to charge a capacitor C_6 to a level higher than a reference voltage determined by resistors R_3 and R_4 such that a comparator CP_2 provides a "High-level" output.

When, on the other hand, the load is disconnected to discontinue a current through Q_1 (or d_1), capacitor C_8 will discharge through resistor R_{11} down to a voltage below the reference voltage at CP_3 , thereby producing a "Low-level" output from CP_3 . Also in the off-load condition, no current flows through Q_2 (or d_2), capacitor C_6 will discharge through resistor R_8 down to a voltage below the reference voltage at CP_2 , thereby producing a "Low-level" output from CP_2 . The outputs from CP_2 and CP_3 are gated at NAND-gate G_{11} to finally provide the load signal NL which goes "High" when any one of the outputs from CP_2

and CP_3 is "Low", and which goes "Low" only when both outputs are "High", thus assuring reliable off-load and on-load or reconnected load detection.

Further, for detecting the re-connection of the load in the circuit of FIG. 36, it may be also effective to operate only one of switching transistor Q_1 and Q_2 after detection of the off-load. For example, when only 5 Q_2 is kept to turn on and off at $V_{IN} > 0$ with Q_1 is disabled or kept turned off irrespective of the input voltage polarity, capacitor voltage V_{C5} at C_5 is kept constantly equal to capacitor voltage ($-V_{C3}$) at C_3 and a current will flow only for a short time period ST after the first reversal of voltage polarity following the detection of the off-load condition, as seen in FIG. 40, and no current will flow until the load is reconnected. With this scheme, therefore, the reconnected condition can be detected by monitoring a current in the 10 circuit only at one point and simply by ignoring the current appearing within such initial short time period ST subsequent to the first polarity reversal of the input voltage, which makes it possible to simplify a control circuit arrangement. Although the above scheme is not capable of detecting the re-connected load condition while $V_{IN} < 0$, such condition can be detected successfully in the subsequent half cycle of $V_{IN} > 0$ and such delay is of no consequence in the actual use. It is of course equally possible to keep only operative Q_1 in 15 contrast to the above explanation. It should be noted at this time that the above control scheme is also applicable to the circuit of FIG. 28.

Referring to FIG. 41, a further arrangement is shown for detection of the input voltage polarity and the off-load condition in the like chopper/inverter circuit. The input voltage polarity is detected at points [M-N] in the same manner as described hereinbefore with reference to FIG. 38. In this modification, a voltage divider 20 of resistors R_{12} and R_{13} is coupled across the series circuit of capacitors C_2 and C_3 so as to provide a monitor output voltage between points [P-G] for detection of the off-load condition and the reconnected load condition by that voltage. Upon occurrence of off-load condition, the chopper output will be all stored in capacitors C_2 and C_3 without being consumed by the load to thereby correspondingly increase capacitor voltage and the monitor voltage [P-G]. Therefore, the off-load condition can be easily detected by the 25 increase in the monitor voltage. At this occurrence, the chopper operation is inhibited by controlling to disable one of Q_1 and Q_2 currently responsible for the chopper operation as identified by the polarity signal SGN , as explained hereinbefore. When the load is reconnected, one of capacitors C_2 and C_3 will provide a current through active one of Q_1 and Q_2 to the load and therefore sees a voltage drop which results in a corresponding voltage drop at [P] by which the re-connected load condition can be easily detected.

As shown in FIG. 42, during the off-load condition [starting from t_0] in which the chopper operation is controlled to be disabled by turning off the corresponding one of the switching transistors responsible for the chopper operation [i.e., Q_1 in positive half cycle and Q_2 in the negative half cycle of V_{IN}], it may be effective to keep on the other switching transistor responsible only for the inverter operation [i.e., Q_2 in the positive half cycle and Q_1 in the negative half cycle of V_{IN}] rather than to turn on and off. With this control, 35 power requirement for driving the switching transistors can be reduced, particularly in the circuit utilizing power MOSFET as Q_1 and Q_2 which requires charging and discharging at gate each time it is turned on and off. Also in this control, drive signals S_1 and S_2 (for Q_1 and Q_2) are apparently to be inverted signal of the polarity signal SGN during the off-load condition, as seen in the figure. Such drive signals S_1 and S_2 can be generated by a logic circuit of FIG. 43. It should be noted in this connection that this control can be 40 well adapted to the circuits of FIGS. 28, 33, and 36.

FIG. 44 illustrates a further arrangement for detection of the input AC voltage polarity and the off-load condition with regard to a modified chopper/inverter circuit. The modified circuit is similar in configuration to that of FIG. 28 except for particular capacitor location in the inverter. For an easy understanding purpose like numerals are repeated to designate like components serving like circuit operations. In this modified 45 circuit, capacitors C_2 and C_3 are connected in circuit to provide a DC voltage to the input of the inverter. Capacitor C_2 is a smoothing capacitor connected across a series pair of first and second transistors Q_1 and Q_2 , while capacitor C_3 is connected in series with the load L across the first transistor Q_2 .

In operation, when transistor Q_1 is on while transistor Q_2 is off during a positive half cycle of the input 50 AC voltage, the voltage source VS flows a current of increasing magnitude through inductor L_2 , third diode D_3 , transistor Q_1 and back to the voltage source VS to store energy into the inductor L_2 . At the same time, transistor Q_1 also acts to flow a current from capacitor C_2 , through Q_1 , capacitor C_3 , load L , and back to capacitor C_2 to provide a load current in one direction. Subsequently, when transistor Q_1 is off and instead 55 transistor Q_2 is on within the same positive half cycle, inductor L_2 releases its energy through third diode D_3 , capacitor C_2 , diode D_2 , and voltage source VS to accumulate a smoothed DC voltage into capacitor C_4 . At this occurrence, transistor Q_2 operates to flow a current from capacitor C_3 , Q_2 , load L , and back to C_3 , thus providing a load current in the opposite direction.

During the negative half cycle of the input AC voltage, when transistor Q_1 is off while transistor Q_2 is

on, the voltage source V_s flows a current through Q_2 , fourth diode D_4 , inductor L_2 back to V_s to store energy into inductor L_2 . At this occurrence, transistor Q_2 operates to flow a load current in one direction from capacitor C_3 , Q_2 , and load L . Subsequently when transistor Q_1 is on and in steady state Q_2 is off, inductor L_2 releases its energy through V_s , first diode D_1 , capacitor C_2 , fourth diode D_4 and back to inductor L_2 for charging capacitor C_2 , while inductor L_2 also supplies a current through V_s , capacitor C_3 , load L , diode D_4 . At the same time, transistor Q_1 operates to flow a load current in the opposite direction from capacitor C_2 through Q_1 , capacitor C_3 , and load L . In this manner, switching transistors Q_1 and Q_2 repeat alternately conductive and non-conductive for effecting the inverter operation of applying a high frequency AC voltage to load L while at the same time effecting the chopper operation of charging capacitors C_2 and C_3 through inductor L_2 and diode-bridge rectifier of D_1 to D_4 in such a way as to provide the smoothed voltage to the inverter input. Accordingly, it is confirmed in this modified circuit that Q_1 is responsible for the chopper and inverter operations and Q_2 is responsible only for the inverter operation during the positive half cycle and vice versa in the negative half cycle of the input AC voltage. Further, in the modified chopper/inverter circuit, coupling capacitor C_3 is selected to have capacitance larger enough than capacitor C_4 , which is connected in parallel with lamp FL to effect preheating the filament thereof as well as to form a resonance circuit with inductor L_3 in the load, so that it will not influence the resonance circuit. As is known from the above discussion, coupling capacitor C_3 acts to provide a DC voltage to the inverter input when Q_2 is on and also acts to filter a DC component in the load current, and therefore can have less capacitance relative to smoothing capacitor C_2 . For example, the circuit may be designed to have $C_2 = 100 \mu F$, $C_3 = 0.47 \mu F$, $C_4 = 0.0015 \mu F$ when $L_2 = 0.5 mH$, $L_3 = 0.45 mH$ are selected for driving a fluorescent lamp [FCL-32EX/30, by Matsushita Denshi Kogyo, Japan] at a switching frequency of 40 KHz from the input voltage of 100 V.

The above modified circuit may be controlled in the same manner as discussed with reference to FIG. 30 or FIG. 37 for ceasing the chopper operation upon detection of the off-load condition while keeping the inverter active for detection of re-connected load condition. In this respect, it may be preferred to keep operating only Q_1 after the off-load condition for reliable detecting the re-connection of the load, in view of that, even when Q_2 is kept operating in the off-load condition in an attempt to provide a load current from C_3 for detection of re-connection of load, C_3 of less capacitance may be exhausted by natural discharging in the off-load condition and may fail to provide the load current.

The input voltage polarity of the above circuit can be detected by monitoring a voltage between points [J-G] with a like detector circuit as shown in FIG. 34. The off-load condition can be also detected by monitoring a voltage across a resistor R_0 inserted in series with Q_2 with the use of a detector circuit as shown in FIG. 45.

It is noted at this time the above modified chopper/inverter circuit can be equally utilized in the previous embodiments without causing any substantial problem in the control of equalizing the chopper input power W_{IN} and the inverter output power W_{OUT} .

FIG. 46 illustrates another modified chopper/inverter circuit in which an additional resonance capacitor C_5 is connected across the lamp FL . For reliably detecting the re-connection of the load with this circuit, it is also effective to keep operating only Q_1 during the negative half cycle of the input AC voltage. Otherwise, Q_2 would operate to discharge C_3 and C_5 substantially entirely, failing to provide a load current at the subsequent re-connection of the load, thus failing to detect the re-connected load condition. Furthermore, if C_3 and C_5 have been exhausted, they would be charged at the conduction of Q_1 to thereby generate an erroneous load current leading to false detection of the re-connected condition such that the control has to be required to ignore such false current by additional scheme as discussed previously with reference to FIGS. 36 and 37. However, by keeping only Q_1 operative in the negative half cycle of the input AC voltage over the off-load condition, C_3 and C_5 can be charged in a manner as to have a relation $V_{C3} + V_{C5} = V_{C2}$ so that a load current will not flow until the load is reconnected, thus making it possible to detect the reconnected load condition by monitoring a load current flowing through the switching transistor.

It is noted at this time that the various controls described in the above for detection of the re-connected load condition can be equally applicable to all the circuits of the present invention including those of FIGS. 23 and 24.

Fourth embodiment <FIGS. 47 to 56>

55

The power control of the present invention is also applicable to cases where the above chopper/inverter circuit is required to provide a relatively low frequency voltage or current of generally rectangular waveform

of less high frequency component resulting from the high frequency switching of Q_1 and Q_2 . For instance, when the circuit is utilized to drive a discharge lamp DL by a relatively low frequency load current of generally rectangular waveform of less high frequency component, as shown in FIG. 49 in order to avoid acoustic resonance which would occur when the lamp is driven by a high frequency current. FIG. 47
5 illustrates a circuit arrangement for producing the low frequency load current which is identical in configuration to the previous embodiment but in which Q_1 and Q_2 are controlled somewhat differently. That is, as shown FIG. 48, Q_1 turns on and off at a high frequency while Q_2 is kept turned off during the positive half cycle of the input AC voltage V_{IN} and vice versa during the negative half cycle of V_{IN} so as to provide an inverter output V a train of high frequency pulses of which polarity is reversed at a low frequency or in
10 synchronism with the low frequency input AC voltage V_{IN} . The circuit includes a bypass capacitor C_5 which is connected across the lamp DL to pass therethrough substantially all of high frequency component of the inverter output V , thereby applying to the lamp DL a load current I_{LA} , as shown in FIG. 49, which sees only a slight amount of the high frequency component and presents a generally rectangular waveform having the same low frequency of the input AC voltage V_{IN} . With this result, the lamp DL can be driven without causing
15 the acoustic resonance leading to unstable arc and eventually to flickering or extinction of the lamp.

FIG. 50 illustrates another scheme of driving Q_1 and Q_2 of the circuit of FIG. 47 in order to obtain a load current of FIG. 51. The load current is characterized to comprise a low frequency part of generally rectangular waveform of FIG. 49 alternated by high frequency part which appear for a limited time interval T_3 around each polarity reversal of the input AC voltage V_{IN} . Such composite current I_{LA} is found
20 advantageous to operate the lamp DL stably while preventing the unacceptable acoustic resonance. For generating the composite current I_{LA} , the circuit is controlled to operate only one of Q_1 and Q_2 selectively depending upon the polarity of the input AC voltage V_{IN} [Q_1 for time period T_1 of $V_{IN} > 0$, Q_2 for time period T_2 of $V_{IN} < 0$] as discussed in the above with reference to FIG. 48, and at the same time to turn on and off alternately for the limited time interval T_3 around the polarity reversal of V_{IN} .

FIG. 52 illustrates another chopper/inverter circuit for providing a train of high frequency output pulses of which polarity is reverse at a low frequency in synchronism with the input AC voltage. The circuit comprises four switching transistors Q_1 to Q_4 connected in full-bridge configuration and a smoothing capacitor C_0 connected in parallel across the series pair of transistors Q_3 and Q_4 . A load L is illustrated as an inductive load having an inductor and resistor. As shown in FIG. 53, during a first time period T_1 or the positive half cycle of V_{IN} , Q_1 is driven to turn on and off at a high frequency and Q_4 is kept turned on, while the other diagonally opposed Q_2 and Q_3 are kept turned off. In the subsequent time period T_2 corresponding to the negative half cycle of V_{IN} , Q_2 is driven to turn on and off at the same high frequency with Q_3 kept turned on, while Q_1 and Q_4 are kept turned off. Whereby, the inverter can provide to the load a resulting output in the form of a high frequency pulse train of which polarity is reversed at the low frequency in
35 synchronism with the input AC voltage. In this circuit having the full-bridge transistor configuration, the load L can receive a full voltage of the C_0 which almost doubles that obtained in the circuit of FIG. 47. Thus, the above circuit is particularly effective where it is required a high load voltage. In the above control of FIG. 53, Q_3 and Q_4 are driven in synchronism with V_{IN} , however, they can be driven to turn on and off at the same high frequency in synchronism with Q_2 and Q_1 , respectively. In such case, upon turning off of Q_1 and Q_4
40 an energy stored in the inductor of the load L will flow through a closed loop of diode D_5 , capacitor C_0 , diode D_2 , and load L , and upon turning off of Q_2 and Q_3 the energy will from the inductor through another closed loop of diode D_1 , capacitor C_0 , diode D_6 , and the load L . Further, it is equally possible to operate Q_1 and Q_2 to turn on and off alternately over the full period of T_1 and T_2 , while operating Q_3 and Q_4 in synchronism with V_{IN} .

FIG. 54 illustrates an arrangement for balancing the chopper input power W_{IN} and the inverter output power W_{OUT} with regard to the like chopper/inverter circuit of FIG. 47 operating in the like manner of FIGS. 48 or 50 to provide an output of FIGS. 49 or 51. To this end, a power controller 10 is included in combination with an input power sensor 11 and an output power sensor 12. The input power sensor 11 is connected in circuit to monitor a DC voltage across capacitors C_2 and C_3 which is the function of the
50 chopper output voltage and therefore indicative of the chopper input power W_{IN} . The output power sensor 12 is connected in circuit to monitor a load current as indicative of the inverter output power W_{OUT} . Due to the inclusion of a bypass capacitor C_5 connected across the discharge lamp DL for bypassing high frequency component as mentioned previously in the circuit of FIG. 47, the load including inductor L_3 and capacitor C_5 will have a natural frequency f_c rather smaller than and spaced from a switching frequency f at which Q_1 and Q_2 are driven to provide a train of rectangular pulses within each half cycle of V_{IN} . For instance, $f_c = 10 - 20$ KHz at $f = 40$ KHz. Accordingly, W_{OUT} will show a rather gradual change with a change in the switching frequency f within an operational range relative to the case where f_c is close to f - [for example, $f_c = 30$ KHz at $f = 40$ KHz], as seen in FIG. 5A, for providing a high frequency alternating

output. This means that only less difference between W_{IN} and W_{OUT} is caused when varying the switching frequency f in order to regulate W_{OUT} or W_{IN} for dimmer control or compensation for an input AC voltage variation. Therefore, when required to balancing W_{IN} and W_{OUT} in accordance with the control schemes of FIGS. 10 to 14, the amount of variation in the switching frequency f as well as duty ratio D can be retained
 5 rather small, thereby facilitating the control of balancing the W_{IN} and W_{OUT} . For example, when it is required to dim the lamp DL from a maximum light intensity condition of FIG. 55A to a reduced light intensity condition of FIG. 55B, the balancing of W_{IN} and W_{OUT} can be re-established also at the dimmed condition by controlling both of the switching frequency f and duty ratio D in accordance with the control scheme as described with reference to FIGS. 13A and 13B but with less variations in f and D . It is noted at this time
 10 that, as shown in FIGS. 55A and 55B, the resulting output current I_{LA} from the circuit of FIG. 54 can be shaped to have generally rectangular waveform from which high frequency components have been removed by the bypass capacitor C_5 and have a low frequency in synchronism with the input AC voltage V_{IN} .

Also with regard to the above circuit of FIG. 54 operating to provide the low frequency output of generally rectangular waveform, it is equally possible to combine the previously mentioned control of intermittently ceasing the chopper operation to regulate the chopper input power W_{IN} relatively independently of the inverter output power W_{OUT} , as discussed in the second embodiment. In this case, as shown in FIG. 56A, one of Q_1 and Q_2 currently responsible for chopper operation is disabled periodically at a regular interval to reduce W_{IN} . Further, it is also possible to combine the control of detecting the off-load and reconnected load conditions as discussed in the third embodiment of the present invention, in which case,
 20 one of Q_1 and Q_2 responsible for the chopper operation is likewise disabled upon detection of the off-load condition, as shown in FIG. 56B, while the other one of Q_1 and Q_2 is kept operative so that the circuit is ready for provide a load current as soon as the load is reconnected.

In the above embodiments and modifications, although the load is mainly shown to comprise a lamp with inductor and capacitor for easy understanding purposes, the present invention should not be understood to be limited thereto and is equally effective to drive various loads including a resistive load and other inductive loads as exemplarily shown in FIGS. 57A to 57D.

The features disclosed in the foregoing description, in the claims and/or in the accompanying drawings may, both, separately and in any combination thereof, be material for realising the invention in diverse forms thereof.

Claims

1. A power supply comprising:

- a source of AC voltage;
- 5 a chopper including a pair of first and second switching elements and capacitor means, said first and second switching elements operating to turn on and off in order to provide from said AC source voltage a periodically interrupted voltage which is smoothed at said capacitor to provide a resulting smoothed DC voltage thereat;
- an inverter sharing said first and second switching elements in common to said chopper and operating to drive said first and second switching elements to turn on and off in order to provide from said DC voltage of said capacitor means an AC voltage to a load;
- 10 an input power sensor monitoring an input power supplied to said chopper;
- 15 an output power sensor monitoring an output power from said inverter to said load; and power control means which controls to vary at least one of a switching frequency and a duty ratio for said first and second switching elements in accordance with the monitored chopper input power and inverter output power in the direction of equalizing said input and output powers.
2. A power source as set forth in claim 1, wherein
- 15 said power control means operating to vary said switching frequency and duty ratio together in combination for equalizing said chopper input power and said inverter output power while maintaining one of said powers substantially at a fixed level.
3. A power source as set forth in claim 1, wherein
- 20 said power control means operating to drive said first and second switching elements in such a manner as to temporarily cease said chopper operation for regulating said chopper input power supplied from said AC source voltage, and at the same time to vary at least one of said switching frequency and duty ratio.
4. A power source as set forth in claim 1, wherein
- 25 said power control means operating to drive said first and second switching elements in such a manner as to temporarily cease said chopper operation while keeping said inverter operation active for regulating said chopper input power supplied from said AC source voltage; and at the same time to vary at least one of said switching frequency and duty ratio.
5. A power source as set forth in claim 1, further including a load detector for detecting whether said load is disconnected from said power source, and including control means operating to drive, in response to a no-load condition detected at said detector, said first and second switching elements in such a manner as
- 30 to cease the chopper operation while keeping the inverter operation, enabling said inverter ready to provide a current when said load is re-connected, and said control means operating, in response to the detection of said current to said load, to resume said chopper and inverter operation.
6. A power source as set forth in claim 1, wherein said first and second switching elements are connected in series across said AC voltage source and driven to alternately turn on and off at a high frequency for switching said DC voltage to provide a high frequency AC voltage; and wherein
- 35 and wherein said chopper includes a diode bridge full-wave rectifier providing a DC voltage from said AC source voltage;
- said rectifier comprising a series connected pair of first and second diodes and another series connected pair of third and fourth diodes in parallel with said pair of first and second diodes, said first and second diodes connected in anti-parallel relation respectively with said first and second switching elements, said first and second diodes defining therebetween a first point of connection, said third and fourth diodes defining therebetween a second point of connection;
- 40 said chopper further including inductor means connected in series with said AC voltage source between said first and second points of connection, whereby said chopper operating to repeat interrupting an AC voltage from said AC voltage source so as to develop at said inductor means a resulting voltage and allow the resulting voltage to be fed through said full-wave rectifier for providing said DC voltage to said capacitor means.
- 45 7. A power supply as set forth in claim 1, wherein said first and second switching elements are connected in series across said AC voltage source and driven to turn on and off at a high frequency for switching said DC voltage to provide a resulting AC voltage; and wherein
- 50 said chopper includes a diode bridge full-wave rectifier providing a DC voltage from said AC source voltage; said rectifier comprising a series connected pair of first and second diodes and another series connected pair of third and fourth diodes in parallel with said pair of first and second diodes, said first and second diodes connected in anti-parallel relation respectively with said first and second switching elements, said first and second diodes defining therebetween a first point of connection, said third and fourth diodes defining therebetween a second point of connection; said chopper further including inductor means connected in series with said AC voltage source between said first and second points of connection, whereby said chopper operating to repeat interrupting an AC voltage from said AC voltage source so as to

develop at said inductor means a resulting voltage and allow the resulting voltage to be fed through said full-wave rectifier for providing said DC voltage to said capacitor means; said inverter operating in synchronism with the polarity of said input AC voltage to keep turning on and off one of said switching elements to which a forward bias is applied from said AC voltage while keeping turning off the other switching element for a suitable time period within each half cycle of said input AC voltage.

8. A power source as set forth in claim 6 or 7, wherein said power control means includes a source voltage polarity detector for identifying which of said first and second switching elements currently receives a forward bias from said AC voltage source and acts both for said chopper and inverter operations, said power control means operating to temporarily cease operating one of said first and second switching elements identified as responsible for both of said chopper and inverter operations while keeping the other switching- element active, whereby regulating said chopper input power supplied from said AC source voltage and at the same time varying at least one of said switching frequency and duty ratio.

15 9. A power source as set forth in claim 6 or 7, further including a load detector for detecting whether
said load is disconnected from said power source, and a source voltage polarity detector for identifying
which of said first and second switching elements currently receives a forward bias from said AC voltage
source and acting currently for effecting both of said chopper and inverter operations, and including control
means operating, in response to a no-load condition detected at said detector, to cease one of said first and
second switching elements identified as responsible for said chopper and inverter operation while keeping
the other switching element active, whereby enabling said inverter ready to provide a current when said
load is re connected, and said control means operating, in response to the detection of said current to said
load, to resume driving said the one switching transistor.

10. A power source as set forth in any one of claims 6 to 9, wherein
said capacitor means comprises a pair of first and second capacitors connected in series across said first
and second switching elements with each of said first and second capacitors connected in series with said
load across each of said first and second switching elements.

(54) Power supply.

(57) An improved inverter AC power supply comprises a chopper providing a DC voltage from an AC source voltage and an inverter providing from the DC voltage a high frequency AC voltage to a load. The chopper comprises a pair of first and second switching elements operating to turn on and off for obtaining a periodically interrupted AC voltage which is rectified and smoothed to provide the DC voltage to the inverter. The inverter is arranged to share the first and second switching elements in common to the chopper and operates to drive the same switching elements for switching the DC voltage in order to

provide a desired AC voltage to the load. The power supply is provided with an input power sensor monitoring an input power supplied to the chopper and an output power sensor monitoring an output power from the inverter to the load. A power controller is included for controlling to vary at least one of a switching frequency and a duty ratio for the first and second switching elements in accordance with the monitored chopper input power and inverter output power in the direction of equalizing the input and output powers.
